**Abstract (resumen de 100-250 palabras)**

Year 2015 was supposed to be a year of economic recovery after one of the biggest economic and financial crisis. However, many Spaniards complained that recovery was not reaching households and that more inequality was been created. That is why the objective of this study is to analyze the perception of the personal economic situation of Spaniards by letting aside macroeconomic data that may not reflect the real situation in Spanish households. It is also important to contrast those inequalities that were said to be created in Spain are real. So, another objective is to detect the differences in the perceptions of economic situation depending on gender, age, region and political ideology among others. To do so, different independence analyses were performed, as well as non-parametric analysis and descriptive analysis of the surveys that were matter of study. Those analyses showed that there are many factors associated with the perception of the personal economic situation such as age, region, political ideology, studies or type of job. Inequalities among the different groups whose factor conform were detected too. Finally, the results of the survey were not as good as one may expect for a year of economic recovery.
